executeTransactionBlock

Execute a transaction, committing its effects on chain.

- `txBytes` is a `TransactionData` struct that has been BCS-encoded and then Base64-encoded.
- `signatures` are a list of `flag || signature || pubkey` bytes, Base64-encoded.

Waits until the transaction has reached finality on chain to return its transaction digest, or returns the error that prevented finality if that was not possible. A transaction is final when its effects are guaranteed on chain (it cannot be revoked).

There may be a delay between transaction finality and when GraphQL requests (including the request that issued the transaction) reflect its effects. As a result, queries that depend on indexing the state of the chain (e.g. contents of output objects, address-level balance information at the time of the transaction), must wait for indexing to catch up by polling for the transaction digest using `Query.transactionBlock`.

```
executeTransactionBlock(
    txBytes: String!
    signatures: [String!]!
): ExecutionResult!
```

Arguments

`executeTransactionBlock.`**`txBytes`**`.``String!` **non-null** **scalar**

`executeTransactionBlock.`**`signatures`**`.``[String!]!` **non-null**
scalar

Type

`ExecutionResult` **object**

The result of an execution, including errors that occurred during said execution.
